In [62]: birds = pd.read_csv("bird_tracking.csv")
          Are there differences in the altitudes of the Birds? Are there futher differences
          when factoring in time of day?
          First, we establish "night" as 6pm to 5am, with day being everything else -- we make a column in the data frame to specify the time of day as "night" or "day",
          and additionally make separate data frames for day and night values.
          Next, we create a new column for altitude, compressing our altitude values down to a more intuitive scale by utilizing the log function. All altitudes equal to or
          less than zero are simply put as 1.
In [63]: birds["Time of Day"] = birds.apply(lambda birds: "Night" if ((pd.to_datetime(birds["date_time"]).hour >= 18) | (pd.to_
          datetime(birds["date time"]).hour <= 5)) else "Day", axis = 1)</pre>
          birds night = birds[birds["Time of Day"] == "Night"]
          birds day = birds[birds["Time of Day"] == "Day"]
          def convert_log(value):
               return numpy.log2(value)
          birds["altitude size marker"] = birds.apply(lambda d: convert log(d["altitude"]) if d["altitude"] > 0 else 1, axis = 1
          For analysis, we determine the average altitude for each bird in general, during the day, and during the night.
In [64]: birds.groupby("bird_name")["altitude"].mean().to_frame().reset_index()
Out[64]:
             bird_name
                          altitude
           0 Eric
                        60.249406
           1 Nico
                        67.900478
           2 Sanne
                        29.159922
In [65]: birds_day.groupby("bird_name")["altitude"].mean().to_frame().reset_index()
Out[65]:
                          altitude
             bird_name
                        67.478760
           0 Eric
           1 Nico
                        77.119432
           2 Sanne
                        30.493537
In [66]: birds_night.groupby("bird_name")["altitude"].mean().to_frame().reset_index()
Out[66]:
             bird_name
                          altitude
                        50.772589
           0 Eric
           1 Nico
                        55.696446
           2 Sanne
                        27.385665
          Clearly, Nico likes to fly the highest, with Eric not too far behind. Sanne, compared to the other birds, likes to fly at much lower altitudes.
          When factoring in day or night, it is clear that Nico and Eric fly lower during the night. Sanne, on the other hand, appears to not have a preference for altitude
          depending on time of day.
          We can illustrate these themes in a boxplot.
In [67]: fig_altitude_time = px.box(birds, x = "bird_name", y = "altitude size marker", color = "Time of Day")
          fig_altitude_time.show()
                                                                                                                                  Time of Day
                                                                                                                                   Night
                   12
                                                                                                                                   Day
              altitude size marker
                                     Eric
                                                                        Nico
                                                                                                           Sanne
                                                                     bird_name
          Now, let's do the same thing for speed.
In [68]: birds.groupby("bird_name")["speed_2d"].mean().to_frame().reset_index()
Out[68]:
             bird_name
                        speed_2d
           0 Eric
                        2.300545
           1 Nico
                        2.908726
           2 Sanne
                        2.450434
In [69]: birds_day.groupby("bird_name")["speed_2d"].mean().to_frame().reset_index()
Out[69]:
             bird_name | speed_2d
           0 Eric
                        2.589002
           1 Nico
                        3.175397
           2 Sanne
                        2.593278
          birds_night.groupby("bird_name")["speed_2d"].mean().to_frame().reset_index()
Out[70]:
             bird_name | speed_2d
           0 Eric
                         1.922081
           1 Nico
                        2.555752
           2 Sanne
                        2.259649
          Nico appears to travel the fastest out of any of the birds, with Sanne next and Eric being the slowest. All the birds travel faster during the day than during the
          night, but again, Sanne appears to have less of a preference depending on the time of day than the other two birds.
          Again, we can visualize this in a boxplot. Since there are many outliers for speed, we limit the y-axis to just range 1 to 10.
In [71]: fig_speed_time = px.box(birds, x = "bird_name", y = "speed_2d", color = "Time of Day")
          fig_speed_time.update_layout(yaxis_range=[0,10])
           fig_speed_time.show()
                   10
                                                                                                                                  Time of Day
                                                                                                                                   Night
                                                                                                                                   Day
              speed_2d
                                                                        Nico
                                                                                                           Sanne
                                                                     bird_name
          What about the maximums?
Out[72]:
             |bird_name | speed_2d
           0 Eric
                        63.488066
           1 Nico
                        48.381510
           2 Sanne
                        57.201748
In [73]: birds_day.groupby("bird_name")["altitude"].max().to_frame().reset_index()
Out[73]:
             bird_name altitude
           0 Eric
                        4639
           1 Nico
                        6965
           2 Sanne
                        6145
          Interestingly, there seems to be an inverse relationship with the maximums of the birds' speed and altitude. Eric has the fastest recorded speed, but the lowest
          maximum altitude. Conversely, Nico has the highest recorded altitude, but the lowest maximum speed. Lastly, Sanne places in the middle with regards to both.
          Furthermore, despite being the slowest bird on average, Eric has the fastest maximum speed. Also, despite being the lowest flying bird on average, Sanne
          does not have the lowest maximum altitude.
          Does Terrain Type affect speed and altitude for each bird?
          Here, we add a new column to the data frame based on the function below, which takes input coordinates and returns if the location is land. Thus, we can
          make a new column telling us whether each point is over land or over water, and make separate data frames based off this condition as well.
In [74]: def over_water(lat, long):
               if globe.is_land(lat, long) == True:
                   return "Over Land"
               else:
                   return "Over Water"
          birds["Terrain"] = birds.apply(lambda x: over_water(x["latitude"], x["longitude"]), axis = 1)
          birds land = birds[birds["Terrain"] == "Over Land"]
          birds water = birds[birds["Terrain"] == "Over Water"]
In [75]: birds_land.groupby("bird_name")["speed_2d"].mean().to_frame().reset_index()
Out[75]:
             |bird_name|speed_2d
           0 Eric
                        2.416903
           1 Nico
                        2.646650
           2 Sanne
                        2.076279
In [76]: birds_water.groupby("bird_name")["speed_2d"].mean().to_frame().reset_index()
Out[76]:
             bird_name | speed_2d
           0 Eric
                        2.160883
           1 Nico
                        3.195355
           2 Sanne
                        3.117444
In [77]: fig speed terrain = px.box(birds, x = "bird name", y = "speed 2d", color = "Terrain")
           fig_speed_terrain.update_layout(yaxis_range=[0,10])
          fig speed terrain.show()
                   10
                                                                                                                             Terrain
                                                                                                                                 Over Land
                                                                                                                                 Over Water
                    8
                    6
              speed_2d
                    2
                    0
                                    Eric
                                                                      Nico
                                                                                                       Sanne
                                                                  bird_name
          Over land, Sanne is by far the slowest bird on average, which is somewhat surprising because Sanne was the middle bird with overall speed. Eric is the only
          bird that travels faster over land than over water, as the other birds travel much faster over water. Nico places as the fastest bird in each category, which makes
          sense considering Nico is the fastest bird overall on average.
          Now let's see altitude.
In [78]: birds_land.groupby("bird_name")["altitude"].mean().to_frame().reset_index()
Out[78]:
             bird_name
                           altitude
           0 Eric
                        88.355298
           1 Nico
                        112.883111
           2 Sanne
                        34.335213
In [79]: birds_water.groupby("bird_name")["altitude"].mean().to_frame().reset_index()
Out[79]:
                          altitude
             bird_name
                        26.469188
           0 Eric
           1 Nico
                        18.834587
           2 Sanne
                        19.891709
In [80]: fig_altitude_terrain = px.box(birds, x = "bird_name", y = "altitude size marker", color = "Terrain")
           fig_altitude_terrain.show()
                                                                                                                             Terrain
                                                                                                                                 Over Land
                   12
                                                                                                                                  Over Water
                   10
              altitude size marker
                                    Eric
                                                                      Nico
                                                                                                       Sanne
                                                                   bird name
          Nico, being the bird that flys highest on average, unsurprisingly flys the highest on average while over land. However, Nico flys over water at the lowest altitude
          on average. Again, we can see that out of all the birds, Sanne has the least variation of altitude. There is not a huge difference between Sanne's average
          altitudes over land or over water. But, it is clear that all the birds do fly lower over water to some extent.
          So, to recap:
          Nico:
              -On average, travels at the highest altitude and highest speed of all 3 birds
              -Has the highest maximum altitude, but surprisingly has the lowest maximum speed
              -Highest average altitude over land, but the lowest average altitude over water
              -Has the highest average speed over land and over water
          Eric:
              -Places in the middle in average altitude, both during the day and night
              -Slowest bird on average (regardless of time of day), yet has the fastest maximum speed
              -Lowest maximum altitude by a wide margin, despite average altitude placing in the middle
              -Only bird to travel faster over land than over water
              -Places in the middle for average altitude over land, but has the highest average altitude over water
          Sanne:
              -Lowest average altitude regardless of time of day by a huge margin, yet has 2nd highest maximum altitude
              -Places in the middle for speed regardless of time of day, and places in the middle for maxiumum speed as well
              -By far the slowest bird on average over land, but essentially tied for the fastest bird on average over water
              -By far the lowest flying bird on average over land, but is not the lowest flying bird on average over water
              -Least amount of variance in altitude regardless of condition by a considerable amount
          Factoring in Distances
          To examine any possible differences in the distances covered by the birds, we can make a data frame comparing distances and time of day.
          To do this, we can build functions to calculate distances between points, and furthermore calculate the absolute value of the distance covered by each bird.
In [81]: def distance(lon1, lat1, lon2, lat2):
               lon1, lat1, lon2, lat2 = map(radians, [lon1, lat1, lon2, lat2])
               dlon = lon2 - lon1
               dlat = lat2 - lat1
               a = \sin(d \cdot at/2) **2 + \cos(at1) * \cos(at2) * \sin(d \cdot at/2) **2
               c = 2 * asin(sqrt(a))
               r = 6371
               return c * r
          def get_dist_bird(bird, df):
               new_df = df[df["bird_name"] == bird]
               new_df = new_df.assign(date=lambda d: pd.to_datetime(d['date_time']))
